Proposal for Test Client

Prepared on 24 September 2026

DOCUMENT Business Proposal	**CLIENT** Test Client

Overview

This proposal outlines a software system to automate the management of service requests and complaints for an HVAC service company. The system will replace manual tracking and assignment processes with a centralized platform, providing real-time status updates for service requests, automated daily reporting for technicians and managers, and email alerts for pending cases. The solution is designed to reduce administrative overhead and improve resource utilization for the client's 10 to 12 staff members.

Client Requirements

- A software system for managing service requests and complaints for air conditioning services.
- The system must track the status of service requests (e.g., where it reached, if it is done or finished).
- Generate daily reports for each technician detailing their work activities, service requests attended, closed, service charges collected, and new products sold.
- The system must send emails to the manager for tracking service requests, including which cases are pending.

Variations in Schema

- The system must automatically assign service requests to technicians based on their current location and availability.
- Technicians with negative feedback or unresolved returns must not be assigned to new service requests.
- The system must generate daily reports for each technician detailing their work activities, service requests attended, closed, service charges collected, and new products sold.
- A WhatsApp chatbot implementation.

Proposed Solution

The proposed solution is a centralized software platform that digitizes and automates the client's HVAC service request management workflow. It will replace manual desk-based tracking and assignment with a digital dashboard. The system will maintain a live status log for every service request, allowing the client to monitor progress from initiation to completion. To address the need for performance tracking and managerial oversight, the system will generate and distribute automated daily reports to technicians and managers. Additionally, the platform will include an email notification module to alert managers regarding pending service requests, ensuring timely follow-up.

Scope of Work

- The implementation scope covers the development of a software system tailored to the verified requirements of the HVAC service company. This includes:
- Developing a service request tracking module to log, update, and monitor the status of incoming AC service requests and complaints.
- Configuring an automated daily report generation and distribution system for technicians, detailing work activities, service requests attended, closed, service charges collected, and new products sold.
- Implementing an email notification system to send tracking updates and pending case alerts to the manager.

- Establishing the necessary database architecture and user interface for the client's staff to access the system.

Business Cost & Efficiency Impact

An AC service company with 10 to 12 staff members who handle incoming service requests and complaints manually, leading to tracking, assignment, and reporting inefficiencies.

Business Area	Current Driver	Automation Opportunity	Impact / Measurement
Service Request Handling	Manual tracking and updating of service request statuses consumes significant staff time.	Implement a software system to automatically track and update the status of service requests.	No reliable estimate could be produced from the meeting or a defensible benchmark. Measure: hours saved per month on manual status tracking Assumption: Benchmark values are illustrative; actual savings depend on current manual process complexity. Basis: Industry benchmark for manual vs automated tracking in field service management. Cannot calculate savings without knowing the time spent per request and the monthly request volume.
Technician Assignment	Manual assignment of service requests to technicians is inefficient and leads to suboptimal resource utilization.	Implement an automated assignment algorithm that matches service requests to technicians based on location, current workload, and feedback history.	No reliable estimate could be produced from the meeting or a defensible benchmark. Measure: percentage of technicians optimally utilized Assumption: Benchmark values are illustrative; actual utilization depends on current assignment practices. Basis: Industry benchmark for optimal technician load balancing. Cannot calculate the percentage of optimally utilized technicians without knowing how many currently have an optimal load.
Technician Reporting	Lack of automated daily reports for technicians leads to manual reporting and tracking efforts.	Implement a system to generate and send automated daily reports to technicians and managers.	No reliable estimate could be produced from the meeting or a defensible benchmark. Measure: hours saved per month on manual reporting Assumption: Benchmark values are illustrative; actual savings depend on current manual process complexity. Basis: Industry benchmark for manual vs automated reporting in field service management. Cannot calculate savings without knowing the time spent on manual reporting per technician.

Client data required for further calculations: number of service requests per month; time spent manually tracking one service request; number of technicians with an optimal load; time spent manually compiling daily report per technician

Timeline

A written proposal and system requirements document will be delivered to the client for review and approval.

Pricing

The proposed software development cost should be within one lakh (100,000).

Hosting the software on an external server will incur additional costs.

Next Steps

- Following the client's review of the written proposal, we will proceed with the next phase of engagement.
