Proposal for Test Client

Prepared on 25 September 2026

DOCUMENT Business Proposal	**CLIENT** Test Client

Overview

We propose a software system to service air conditioners and handle service requests. This web application will feature staff and admin roles to manage service requests, including automatic assignment of jobs to technicians based on location mapping. The system will track service request statuses, provide follow-up tracking, and send automatic email alerts to managers regarding pending or overdue requests. Technicians will be able to mark attendance in the morning and view their automatically assigned jobs.

Client Requirements

- A software system to service air conditioners and handle service requests.
- A web application with staff and admin options to handle service requests.
- Automatic assignment of service requests to technicians.
- Service requests must be assigned based on the customer's location mapped to the technician's location.
- The system must track the status of service requests (e.g., pending, completed, closed) and provide follow-up tracking.
- The manager must receive emails regarding pending or overdue service requests.
- Technicians must be able to mark attendance in the morning and view their automatically assigned jobs.

Variations in Schema

- The automatic assignment must use an algorithm based on time period, workload, and location; manual assignment is not acceptable.
- The system must automatically assign the request to the nearest technician based on location mapping.
- Technicians with negative feedback, low feedback, or who have returned a service should not be assigned new requests.
- The system must automatically assign new requests based on a time-period algorithm, considering the technician's current workload and location.
- Technicians must view their automatically assigned jobs after marking attendance; the system does not explicitly support automatic assignment of jobs after attendance marking.
- Technicians must have access to a graphical dashboard to view their daily work activities, such as service requests attended, closed, charges collected, and new products sold.
- Implementation of a WhatsApp chatbot.

Proposed Solution

The proposed solution is a custom web application designed to replace the client's manual service request handling and tracking processes. The application will be developed as a web-based platform with distinct staff and admin user interfaces.

For the admin and staff interfaces, the system will provide a centralized dashboard for creating, viewing, and managing incoming service requests. The core functionality will include an automated assignment engine that maps customer locations to technician locations to distribute jobs efficiently.

Technicians will access a dedicated interface where they can mark their daily attendance and view their automatically assigned jobs for the day. The system will maintain a comprehensive status log for each service request, tracking them through pending, completed, and closed stages, and will support follow-up tracking mechanisms. Additionally, the platform will include an automated notification module to send email alerts to managers for any service requests that remain pending or become overdue.

Scope of Work

- The implementation scope will focus on the development and deployment of the verified requirements:
- Development of the web application with staff and admin authentication and interfaces.
- Configuration of the automatic service request assignment module based on mapped customer and technician locations.
- Implementation of the service request status tracking system, including follow-up tracking capabilities.
- Setup of the automated email notification system for managers regarding pending or overdue service requests.
- Development of the technician module for morning attendance marking and viewing assigned jobs.
- Deployment of the application on the client's infrastructure as per the hosting arrangement.

Business Cost & Efficiency Impact

A company with 10 to 12 staff handling air conditioner service requests. They currently manually process and track service requests, leading to time consumption, and want to implement an automated web application for request assignment, tracking, and technician performance monitoring.

Business Area	Current Driver	Automation Opportunity	Impact / Measurement
Service Request Processing	Manual handling of service requests by dedicated staff.	Implement an automated web application to handle service requests, auto-assign them based on location, workload, and time, and track status automatically.	Illustrative scenario If 100 requests/month take 0.5 hours each manually, total time is 50 hours/month. With 90% automation efficiency, time saved is 45 hours/month. Measure: Hours per month saved by staff on manual service request handling and tracking. Assumption: Benchmark values are illustrative and not supported by the meeting.
Technician Assignment	Manual assignment of service requests to technicians, leading to inefficiencies in route planning and workload balancing.	Implement an automatic assignment algorithm based on customer location, technician location, current workload, and time period.	Illustrative scenario If 100 requests/month travel 20 km each manually, total is 2000 km/month. With 15% optimization, saved distance is 300 km/month. Measure: Travel distance or time saved per month due to optimized assignment. Assumption: Benchmark values are illustrative and not supported by the meeting.
Technician Performance Management	Assigning new requests to technicians with negative feedback, low ratings, or returns, leading to potential rework and customer dissatisfaction.	Implement automatic assignment rules to exclude technicians with negative feedback, low ratings, or returns from new request assignments.	Illustrative scenario If 5 problematic technicians handle 100 requests/month with a 20% rework rate, 10 rework incidents could be avoided. Measure: Number of rework incidents or customer complaints avoided per month. Assumption: Benchmark values are illustrative and not supported by the meeting.
Technician Reporting	Manual tracking and reporting of daily work activities (service requests attended, closed, charges collected, new products sold) by technicians.	Implement a graphical dashboard for technicians to view their daily work activities and automatically generate reports.	Illustrative scenario If 12 technicians spend 0.5 hours/day on manual reporting, total is 180 hours/month. With 0.1 hours/day automated, saved is 144 hours/month. Measure: Hours per month saved by technicians on manual reporting. Assumption: Benchmark values

			(days per month) are illustrative and not supported by the meeting.
System Notifications	Lack of automated email notifications for pending or overdue service requests to managers.	Implement automatic email notifications to managers for pending or overdue service requests.	Illustrative scenario If managers spend 0.1 hours per check and check 20 times/month, total is 2 hours/month. With automated notifications, saved is 2 hours/month. Measure: Hours per month saved by managers on manual status checking. Assumption: Benchmark values are illustrative and not supported by the meeting.
WhatsApp Chatbot	Manual handling of customer inquiries via WhatsApp without an automated chatbot.	Implement a WhatsApp chatbot for customer service requests.	Illustrative scenario If 50 inquiries/month take 0.05 hours each manually, total is 2.5 hours/month. With chatbot handling 0.01 hours each, saved is 2 hours/month. Measure: Hours per month saved by staff on manual WhatsApp handling. Assumption: Benchmark values are illustrative and not supported by the meeting.

Client data required to replace illustrative assumptions: Hours spent per manual service request; Number of service requests per month; Average distance per service request; Rework rate for problematic technicians; Number of technicians with negative feedback or returns; Time spent by technician on manual reporting per day; Time spent by manager per manual status check; Number of manual status checks per month; Time spent by staff per WhatsApp inquiry; Number of WhatsApp inquiries per month

Timeline

[To be inserted by Python]

Pricing

The proposed solution should cost approximately one lakh (100,000).

Hosting the application on the client's own server will not incur additional charges, but providing a server from the developer will incur an additional cost.

Next Steps

- We look forward to discussing the project details further and outlining the immediate steps required to initiate the development process. Please let us know a suitable time to connect.
