Proposal for Test Client

Prepared on 25 September 2026

DOCUMENT Business Proposal	**CLIENT** Test Client

Overview

This proposal outlines the development of a web application to automate the management of air conditioning service requests and complaints for an HVAC company. The solution will replace manual dispatch and tracking processes, enabling automated technician assignment, real-time progress tracking, and automated manager notifications within an approximate budget of one lakh.

Client Requirements

- The system must handle service requests and complaints for air conditioning services.
- Service requests must be automatically assigned to technicians based on their location and availability.
- The system must track the progress of service requests, including status updates and completion.
- Managers must receive email notifications for pending service requests.

Variations in Schema

- based on their location and availability
- Technicians who have received negative feedback or returns should not be assigned new service requests.
- The system must calculate and report on daily technician work activities, including requests attended, closed, charges collected, and new products sold.
- Implement a WhatsApp chatbot for HVAC-related service requests.

Proposed Solution

The proposed solution is a fully automated web application designed to manage service requests and complaints. It will replace the current manual dispatch and tracking system by implementing an automated assignment algorithm that allocates service requests to technicians based on location and availability. The application will provide real-time tracking of service request progress, including status updates and completion. Additionally, the system will automatically send email notifications to managers for any pending service requests, ensuring timely oversight and intervention.

Scope of Work

- Development of a web application to receive and process service requests and complaints.
- Implementation of an automated assignment module that matches incoming requests to technicians based on location and availability.
- Configuration of a tracking module to monitor the status and completion of service requests.
- Setup of an email notification system to alert managers of pending service requests.

Business Cost & Efficiency Impact

An air conditioning service company with 10 to 12 staff members handling service requests and complaints. They currently manually assign jobs and track progress, and they are seeking a fully automated web application to manage assignments, tracking, and reporting.

Business Area	Current Driver	Automation Opportunity	Impact / Measurement

Service Request Assignment & Dispatch	Dedicated staff time spent on manual dispatch and tracking of service requests.	Automated assignment of service requests to technicians based on location and availability, with automatic status updates and email notifications to managers for pending requests.	Illustrative scenario If the dedicated staff member works 160 hours/month and automation saves 90% of their time, the saved hours would be 160 * 0.9 = 144 hours/month. Measure: Total hours saved per month by reallocating the dedicated staff member to other tasks. Assumption: No benchmark values are assumed. The calculation cannot be performed due to missing inputs.
Daily Technician Work Activity Reporting	Manual compilation of daily reports for technicians (requests attended, closed, charges collected, new products sold) and sending them via email to a specific office mail ID.	Automated generation and emailing of daily graphical reports of technician work activities to the office mail ID.	Illustrative scenario If the manager spends 1 hour per day on reports for 22 working days a month, the saved time would be 22 hours/month. Measure: Total hours saved per month by the manager in compiling and sending daily reports. Assumption: No benchmark values are assumed. The calculation cannot be performed due to missing inputs.
Technician Availability & Workload Management	Manual checking of a technician's current workload (e.g., number of assigned requests, completion status) before assigning a new request, which can lead to inefficient allocation and delays.	Automated assignment algorithm that checks a technician's current workload and availability in real-time before assigning a new request.	Illustrative scenario If 100 requests are received in a month and 80 are assigned to available technicians, the capacity recovery rate is (80 / 100) * 100 = 80%. Measure: Percentage of requests assigned to available technicians, reducing idle time and delays. Assumption: No benchmark values are assumed. The calculation cannot be performed due to missing inputs.

Client data required to replace illustrative assumptions: Dedicated staff member's monthly working hours; Manager's daily time spent on report compilation; Number of working days per month; Total number of service requests per month; Number of requests assigned to available technicians; Current percentage of requests assigned to available technicians

Timeline

No specific timeline information was provided.

Pricing

The project should be completed within an approximate budget of one lakh.

Server hosting will incur an additional cost if the client does not provide their own server.

Next Steps

- Review and approve the proposed scope of work and commercial terms.
- Schedule a technical discovery session to discuss server hosting requirements and finalize project milestones.
